Background: Small cell lung cancer (SCLC) is highly invasive and fatal, sensitive to chemotherapy and radiotherapy but prone to relapse, with a poor overall survival rate. It is particularly urgent for SCLC patients to receive effective follow-up treatment. In the past 20 years, there has been no breakthrough in clinical treatment of SCLC. Currently, clinical studies on immunotherapy for SCLC with extensive stage disease (ED) have achieved good efficacy, bringing new hope for the treatment of small-cell lung cancer. PD-1 inhibitors used to treat small cell lung cancer include Pembrolizumab and Nivolumab. PD-L1 inhibitors mainly include Atezolizumab and Durvalumab. Other PD-1/PD-L1 inhibitors, such as Avelumab, are currently being tried for SCLC and the results have not yet been published. This study is to evaluate the efficacy and safety of immunotherapy in patients with ED SCLC.

Methods: A literature search of the PubMed, Embase, and Cochrane Library databases were performed. Two reviewers independently screened the literature, extracted the data, and evaluated the risk of bias of the included studies. RevMan 5.3 software was used for meta-analysis.

Results: Four studies involving 1,981 patients with ED SCLC were included. Both overall survival (OS) [hazard ratio (HR) =0.80, 95% confidence interval (CI) (0.68, 0.95), P=0.009] and progression-free survival (PFS) [HR =0.82, 95% CI (0.75, 0.90), P <0.00001] were longer in the immunotherapy group than in the chemotherapy group. The incidence of total treatment-related adverse events in the immunotherapy group were lower than those in the chemotherapy group [relative risk (RR) =1.050, 95% CI (1.010, 1.080), P=0.007], and the differences were statistically significant.

Conclusions: Immunotherapy has better efficacy and safety than chemotherapy for the treatment of ED SCLC.

Keywords: Immunotherapy; chemotherapy; small cell lung cancer

Introduction

In recent years, the incidence and mortality rates of lung cancer have been increasing. Small cell lung cancer (SCLC) accounts for about 15% of all lung cancers, and is highly invasive and fatal due to its rapid growth, abundant stem cells, and gene instability (1). Moreover, at the time of diagnosis, most of the patients are in the extensive stage (when tumor cells have spread beyond the supraclavicular region), and for these patients, the 5-year survival rate is less than 2% (2,3). Due to the slow progress of research and the entry stage of treatment, effective follow-up treatment for SCLC patients is particularly urgent. Etoposide plus cisplatin (EP) chemotherapy is the standard treatment for extensive stage disease (ED) SCLC. Although the response
rate is high, most of the cases recur within one year. Chemotherapy drugs such as irinotecan, cyclophosphamide, adriamycin, and vincristine (CAV) have been used as second-line therapy, but have only produced minor effects (4). With increased research into surgery, radiotherapy, chemotherapy, and targeted therapy, the emergence of immunotherapy may become a new pillar of cancer treatment (5). In some international randomized controlled trials (RCTs), immunotherapy has been shown to be a safe and effective strategy to restore the antineoplastic activity of T lymphocytes at key immune checkpoints, and can be used in patients with advanced or metastatic malignancies (6-10).

At present, immune checkpoint inhibitors stand out from many anti-tumor research, and have made breakthrough progress, and change the clinical practice, with epoch-making significance. The research on SCLC immune checkpoint inhibitors mainly focuses on CTLA-4 inhibitors and PD-1/PD-L1 inhibitors (11). As a negative regulator of T cell activation expressed on the surface of T cells, the cytotoxic T-lymphocyte-associated 4 (CTLA-4) protein competitively inhibits T cell activation with cluster of differentiation 28 (CD28). The combination of CTLA-4 inhibitors and CTLA-4 blocks the interaction between the latter and its ligand (CD80/CD86), which could block the negative regulatory signal of CTLA-4, and thereby enhance the antineoplastic activity of T cells (12). The interaction after the binding of programmed cell death protein 1 (PD-1) and its ligand (PD-L1 or PD-L2) in the host tissue inhibits T cell receptor (TCR) signals. This leads to functional impairment of the effectors in CD4+ and CD8+ T cells, limits the interaction between T cells and target cells, and inactivates T cells and inhibits their proliferative ability (13-15). PD-1/PD-L1 inhibitors can block this negative regulatory signal, activate CD8+ T cells (TEX) with low function, and restore their anti-tumor function, thereby enhancing the immune response (16).

Keynote-028 study showed that pembrolizumab had good anticancer activity in PD-L1 positive patients with extensive SCLC, and the objective remission rate could reach 33%. The national comprehensive cancer network (NCCN) guidelines recommend ipilimumab and nivolumab for refractory patients (category 2a) who have been treated for less than 6 months from treatment to recurrence (17). An open, randomized, phase III study of nivolumab controlled chemotherapy for relapsed SCLC after first-line platinum containing chemotherapy regimen is under way in the ongoing phase III clinical trial, and the phase III study of PD-L1 inhibitor atezolizumab + carboplatin + etoposide in the treatment of extensive stage SCLC is under way. These results will establish the status of immunotherapy in the combination therapy of ES-SCLC, and search for biomarkers that can predict the benefits from immunotherapy, which will promote the development of this field.

In the aspect of small cell lung cancer, there are few studies on the single immunotherapy, combined chemotherapy and chemotherapy alone, and there are more disputes about the effectiveness and safety of combined treatment, which needs meta-analysis and statistical analysis. This study aims to compare several international large-scale randomized controlled trials (RCTs) related to immunotherapy combined with chemotherapy, and analyze whether the effectiveness and safety are statistically significant, so as to provide treatment reference for readers. We present the following article in accordance with the PRISMA reporting checklist (available at http://dx.doi.org/10.21037/apm-20-2011).

Methods

Data and methods

Inclusion criteria
(I) Studies involving patients diagnosed as ED SCLC by pathology and cytology; (II) clinical trials published comparing ICIs and chemotherapy for the treatment of ED SCLC; (III) randomized controlled trials (RCTs) in phase II or III; (IV) studies exploring more than one main outcome index: overall survival (OS), progression-free survival (PFS), or objective response rate (ORR).

Exclusion criteria
(I) Studies involving patients that received anti-tumor immunotherapy before joining the clinical trial; (II) Studies involving treatment measures such as combined irradiation, molecular targeted therapy, or other ICI treatment; (III) Republished clinical research; (IV) Research with incomplete data or where we were unable to extract the relevant data.

Retrieval strategies
We performed a comprehensive literature search on the PubMed, Embase, and Cochrane Library databases, covering all articles published on these databases up to March 1st, 2020. Our key word search terms involved a combination of subject and free words, including Small Cell Lung Cancer, Oat Cell Lung Cancer, Small Cell Cancer
of The Lung, Carcinoma, Small Cell Lung, Anti CTLA-4 Mab Ipilimumab, MDX-CTLA-4, pembrolizumab, SCH-900475, Keytruda, MK-3475, Lambrolizumab, Atezolizumab, anti-PDL1, MPDL3280A, Tecentriq, RG7446, Durvalumab, MED14736, Imfinzi, Nivolumab, Opdivo, ONO-4538, MDX-1106, BMS936558, CD279 Antigen, PD1 Receptor, Programmed Cell Death 1 Protein, B7 H1 Antigen, CD274 Antigen, B7H1 Immune Costimulatory Protein, etc.

Quality evaluation of included literature
Two reviewers independently screened the literature and evaluated the quality and bias of the included studies according to the standards recommended by the Cochrane manual. The main evaluation methods are shown in Table 1.

Statistical methods
RevMan 5.3 software was used to statistically analyze the data. Hazard ratios (HR) or relative risks (RR) were used as the effect indexes for comparison between the immunotherapy and chemotherapy groups. Point estimates and 95% confidence intervals (CI) of each effect size were given. We tested the statistical heterogeneity of the included studies using the $I^2$ statistic. Studies were considered to show no statistical heterogeneity if $P>0.10$ and $I^2<50\%$, and a fixed effects model was used for combined analysis. However, $P \leq 0.10$ or $I^2 \geq 50\%$ indicated a statistical heterogeneity among the studies, and a random effects model was employed. Significant clinical heterogeneity was examined by subgroup, sensitivity, or descriptive analysis. Differences were statistically significant at $P<0.05$.

Results

Literature screening results
A total of 2,282 articles were initially screened. These articles were examined further by reading the titles and abstracts. Finally, four clinical RCTs in phase II or III were included in the meta-analysis (Figure 1).

Basic information of the included studies
A total of four RCTs involving 1,981 patients with ED SCLC were selected for our meta-analysis, including 989 cases in the immunotherapy group and 992 cases in the chemotherapy group. The basic information of the included studies are shown in Table 2. Briefly, Horn et al. (18) is a RCT comparing atezolizumab and chemotherapy; Paz-Ares et al. (19) included two subgroups: durvalumab + tremelimumab + platinum/etoposide and durvalumab + platinum/etoposide. From this paper, only a comparison between the durvalumab group and chemotherapy group was included; Reck et al. (20) is a RCT comparing ipilimumab and chemotherapy. In this paper, only the staged groups were included in the analysis (although the original text included two simultaneous and staged subgroups); Martin Reck et al. (21) is a phase III RCT comparing ipilimumab and chemotherapy.

Quality of the included studies
The sample sizes of the four RCT studies were sufficient, and the randomized controlled method was adopted. All four studies were open trials and were performed in accordance with the principle of random distribution. The data were complete without selectively reporting results. However, it was unclear whether there was distribution hiding or other biases.

Meta-analysis results

Overall survival (OS)
All four RCTs reported OS. Meta-analysis using a random
effects model showed that the OS of the immunotherapy group was higher than that of the first-line chemotherapy group in the treatment of SCLC, and the difference was statistically significant [HR =0.80, 95% CI (0.68, 0.95), P=0.009, Figure 2].

PFS

All four RCTs reported PFS. Meta-analysis using a random effects model showed that the PFS of the immunotherapy group was higher than that of the first-line chemotherapy group in the treatment of SCLC, and the difference was statistically significant [HR =0.82, 95% CI (0.75, 0.90), P<0.00001, Figure 3].

ORR

All four RCTs reported ORR. Meta-analysis using a random effects model showed that there was no significant difference between the immunotherapy group and the first-line chemotherapy group in the treatment of SCLC [RR =1.04, 95% CI (0.93, 1.17), P=0.46, Figure 4].
Adverse reactions

All four RCTs reported treatment-related adverse reactions. Meta-analysis using a random effects model showed that the adverse reactions of the immunotherapy group were lower than those of the chemotherapy group, and the difference was statistically significant [RR = 1.050, 95% CI (1.010, 1.080), P=0.007, Figure 5]. A subgroup analysis of common adverse reactions was conducted, as shown in Table 3. There were no statistically significant differences except for decreased appetite and decreased white-cell count.

Discussion

Numerous studies have shown that immunosuppression induced by lung cancer cells is a crucial factor in the malignant progression. Immunotherapy can enhance the innate immune response of patients, and is expected to induce a long-term response (22). Chemotherapy has long been considered to be immunosuppressive and incompatible with immunotherapy. In order to improve the low response rate of immune inhibitors (when used alone), some experiments have combined chemotherapy with ICIs,

ED, extensive stage disease; SCLC, small cell lung cancer; RCT, randomized controlled trial.

attempting to utilize the immunomodulatory (synergistic) effect of chemotherapy on tumor and immune cells (23).

In recent years, there have been an increasing number of clinical trials regarding immunotherapy of SCLC. PD-1 inhibitors (nivolumab and pembrolizumab) and PD-L1 inhibitors (durvalumab and atezolizumab) have shown antineoplastic activity and manageable safety in various tumor types (24). The clinical trials currently being conducted, including Keynote-604, Checkmate 331, and NCT02963090, will provide more evidence regarding the treatment of SCLC (5).

In the four clinical trials included in our meta-analysis, both OS and PFS improved, thus reinforcing the combination therapy as a potentially novel strategy for the treatment of SCLC. Among them, the efficacy for ipilimumab + paclitaxel + carboplatin in Reck et al. was significantly improved. However, the OS rate of ipilimumab + chemotherapy was not significantly different from that of chemotherapy alone. This is understandable, considering that ipilimumab targets CTLA-4 to stimulate the activation of peripheral blood T cells, but cannot activate T cells in the tumor microenvironment. In view of this mechanism of action, Reck et al. speculated that the value of ipilimumab on chemotherapy synergistic effect was limited (21). Subsequent studies have shown that nivolumab and ipilimumab may provide a synergistic antitumor effect (25). Combination chemotherapy with ipilimumab, a CTLA-4 inhibitor, did not show obvious synergistic effect, while the PD-1 inhibitor for tumor-infiltrating lymphocytes supplemented the antineoplastic activity of CTLA-
4 inhibitor in a non-redundant way; the related clinical research (Checkmate 451) is currently being conducted (26). The results of IMpower133 (18) and CASPIAN (19) have shown that platinum and etoposide might not deplete T cells in the tumor, and atezolizumab and durvalumab could activate T cells in the tumor and play an anti-tumor role, however this requires further research.

According to the results of our meta-analysis, immunotherapy performed better than chemotherapy in OS HR =0.800, 95% CI (0.680, 0.950), P=0.009] and PFS [HR =0.820, 95% CI (0.750, 0.900), P<0.001]. Furthermore, the incidence of adverse reactions in the immunotherapy group was better than the chemotherapy group [RR =1.050, 95% CI (1.010, 1.080), P=0.007]. This suggests that combining checkpoint inhibition with cytotoxic therapy in induction may be beneficial, with outcomes consistent with international trials. Atezolizumab was launched in China in 2020, and Atezolizumab combined with chemotherapy became the preferred National Comprehensive Cancer Network (NCCN) first-line treatment of ED SCLC (16), providing stronger support for the clinical application of immunotherapy combined with chemotherapy.

The four studies included in this paper were large RCTs with rigorous study designs. However, due to limited immunotherapy studies on SCLC and ongoing partial trials, there were no clear outcome indicators, and thus the number of included studies was relatively small, resulting in bias. Therefore, the efficacy and safety of immunological preparations should be comprehensively assessed and carefully selected.
