Background: Radiotherapy is the cornerstone in cancer treatment, and its adverse effects have been recognized widely nowadays. In response, effective and nontoxic therapies are in demand for patients affected by radiotherapy-induced adverse effects (RIAE). As a multitude of clinical studies have suggested that acupuncture therapies seem to be potential in treating RIAE, this study aims to make a systematic review and Bayesian network meta-analysis (NMA) to evaluate effectiveness and safety of different acupuncture treatments.

Methods: A full-scale search will be performed in the following databases from inception to June, 2020: PubMed/Medline, Cochrane library, Web of Science, Elsevier, Embase, China National Knowledge Infrastructure (CNKI), Wanfang Database, VIP Database and China Biology Medicine disc (CBM). Randomized controlled trials meeting the eligible criteria based on PICOS elements will be included. The primary outcome is the response rate of RIAE or the incidence of RIAE. The secondary outcome is the incidence of adverse events directly related to acupuncture. Cochrane risk-of-bias tool (ROB 2.0) will be employed to evaluate the quality of chosen literatures. Stata, Addis and OpenBUGS will be performed to manage data.

Discussion: The results can provide a relatively objective evidence to assess effectiveness and safety of acupuncture therapies for each RIAE, which may be rewarding as a guiding proposal for researchers concerning RIAE.

Trial registration: This study has been registered at INPLASY (https://inplasy.com/) with a registration ID INPLASY202070054.

Keywords: Acupuncture therapy; radiotherapy-induced adverse effects (RIAE); network meta-analysis (NMA)

Introduction

Radiation therapy is invariably regarded to be pivotal in treatment of cancers, which has been used in more than 50% of patients with cancer, for both curative and palliative purposes (1,2). It undoubtedly comes with radiotherapy-induced adverse effects (RIAE) for cancer patients (3). Adverse effects decrease patients’ life quality and even cause a treatment withdrawal (4). Reducing the radiation dose in normal tissue can control adverse effects, but it brings with low efficiency in the meantime (5-7). Current medications for RIAE either mark adverse effects of their own, or lack of proven specificity (8-11). As an example of pharmacological interventions for radiation-induced salivary gland dysfunction, insufficient evidence determined the effects of interventions like pilocarpine, betahanechol and palifermin (12). Given a long-lasting adverse symptom, coupled with long duration of therapy and expense suggest more promising options, both psychologically and economically (13).

As complementary and alternative therapies, acupuncture-related interventions have been proved positive in treating RIAE these years (14-16). Under the guidance of traditional Chinese medicine (TCM), radiation is regarded as an external toxicity and correspondingly acupuncture therapies can strengthen the body resistance to eliminate pathogenic factors (17,18). Acupuncture is recommended for patients with xerostomia after radiotherapy (19,20). One large-sample meta-analysis described moxibustion can reduce gastrointestinal toxicities of radiotherapy (21). Despite several researches held discrepant attitudes towards different acupuncture therapies (22-24), an updated review could be feasible as researchers have gradually poured attention to this topic. Therefore, we hold the ambition for assessing the efficacy and safety of various acupuncture therapies for different RIAE by performing a Bayesian network meta-analysis (NMA).

We present the following article in accordance with the PRISMA reporting checklist (available at http://dx.doi.org/10.21037/apm-20-1747).

Methods

The Preferred Reporting Items for Systematic review and Meta-Analysis Protocols (PRISMA-P) statement will be performed in this article (25,26).

Eligible criteria

Types of studies
Randomized control trials (RCTs) in peer-reviewed journals will be included. Languages are limited to Chinese and English. Reviews, retrospective studies, case reports, protocols, animal studies, unpublished reports, studies unrelated to acupuncture and RIAE will be excluded. The most informative and complete one of duplicate studies will be included.

Types of participants
Patients received radiotherapy or individuals diagnosed as RIAE will be included, regardless of the type of cancer. Adverse events are embodied in systemic symptoms and local responses, as examples of myelosuppression and xerostomia.

Types of interventions
Acupuncture therapies are listed as interventions, including manual acupuncture, electroacupuncture, moxibustion, acupoint injection, auricular acupuncture, catgut embedding, transcutaneous electrical stimulation and so on. Acupuncture therapies with or without medication will also be counted in. Complete and precise acupoint prescriptions must be described in the literature while there is no limitation in acupoint selection. An example of possible network plot is displayed in Figure 1.

Types of comparisons
The comparisons contain placebo, usual care and medication. Placebo refers to sham acupuncture in most cases while usual care means routine clinical care. Besides, relevant common treatments are also used to treat different adverse events in control groups, which is a rational research design thus such circumstances should be accepted. Take the case of radiation enteritis, enema can be adopted as the comparison treatment. Complementary therapies unconnected with acupoints as comparisons like dietary therapy and aromatherapy will be excluded.

Types of outcome measures

Primary outcome measures
The primary outcome will be the response rate or the incidence of RIAE. Different RIAE will be discussed separately. Here are 2 examples following based on a pre-
search: studies about vomiting and/or nausea caused by radiotherapy regard incidence of vomiting/nausea as the main outcome; studies about xerostomia caused by radiotherapy regard salivary flow rate as the main outcome.

Secondary outcome measures
The incidence of adverse events directly related to intervention as reported to evaluate safety measures will be regarded as the secondary outcome.

Search strategy
PubMed/Medline, Cochrane library, Web of Science, Ebsco, Embase, China National Knowledge Infrastructure (CNKI), Wanfang Database, VIP Database and China Biology Medicine disc (CBM) will be searched from inception to June 2020. The following search keywords and mesh terms will be used: radiotherapy (“radiotherapy” or “radiation therapy” or “cranial irradiation” or “Radiotherapy, Computer-Assisted” and so on); acupuncture (“acupuncture” or “electroacupuncture” or “acupuncture therapy” and so on). The search strategy of different databases will be modified properly. Appendix 1 shows a detailed search strategy for PubMed.

Screening and selection of the RCTs
For the first turn, all searched studies will be independently skimmed through the titles and abstracts by 2 reviewers, under the guidance of Appendix 2. Secondly, the full-text reading of filtered studies will be accomplished to an elaborate selection. The third reviewer will make the final judgement if controversial. Moreover, when full text of literature can’t be found after full-scale search, we will contact with the corresponding author. If we fail to get the full information, the data of this literature will be deleted. The selection process will be carried out in PRISMA flow chart as Figure 2.

Data extraction and management
A standard data extraction excel file will be created in the wake of targeted RCTs, with following information: (I) literature information: title, authors, the country of first author, year of publication, ethical approval and registration state; (II) patient information: sex, sample size, types of cancer, radiation dose, RIAE, types of intervention, types of comparison, intervention time point, endpoints, acupoints; (III) outcome information: the response rate of RIAE, the incidence of RIAE, degree of symptom improvement, observation time points of outcome. Necessary details will be added in the process of data extraction. Two reviewers will complete the task and the third review will act as a referee in the context of ambiguity and divergence. Furthermore, GetData Graph Digitizer will be applied to acquire digital information from figures.

Risk of bias assessment
Cochrane risk-of-bias tool (ROB 2.0) will be used to assess the quality (27). There are 5 sources of bias including bias arising from the randomization process, bias due to deviations from intended interventions, bias due to missing outcome data, bias in measurement of the outcome and bias in selection of the reported result. The final risk of bias can be figured out as 3 degrees: low risk, some concerns and high risk. Two reviewers will evaluate all filtered studies and the third reviewer will make the final decision if controversial.

Data analyses
Pairwise meta-analysis
The premise of Pairwise Meta-analysis is law of similarity, which means only when the included studies meet a certain degree of similarity, can the meta-analysis be carried out. We stipulate that no less than 3 studies of same interventions and outcome indicators can make sense in pairwise meta-analysis. With the tool of Stata 14.0, odds
Identification

Screening

Eligibility

Included

Records after duplicates removed

Records excepted after title and abstract review
- Not clinical trials
- Not cancer patients
- Not related to acupuncture
- Not related to radiotherapy-induced adverse effects
- Not peer-reviewed
- Languages besides Chinese and English

Records screened

Records excepted after full-text review
- Not RCT
- Improper outcomes
- Wrong interventions or comparisons
- Adverse effects not surely caused by radiotherapy
- Sample size <10

Full-text articles assessed for eligibility

Studies included in qualitative synthesis (meta-analysis)

Figure 2 PRISMA flow diagram of the study selection process.

Network meta-analysis

NMA is the development of traditional meta-analysis. In this study, Addis1.16.8, OpenBUGS3.2.3 and Stata14.0 will be performed to present the results. OR and 95% CI will be adopted in the light of incidence, the outcome indicator, as dichotomous data. Addis1.16.8 evaluates the variance of chains by adopting convergence, with PSRF closed to 1 indicating a good convergence. If the P value >0.05, which means an excellent consistency, a consistency model will be used. As to inconsistency test for results, we will monitor the loop formed by studies with both direct evidence and indirect evidence, to figure out whether the inconsistency factor value approximate 0. With a 95% CI, it indicates a slim possibility of inconsistency if 0 is included, thus a consistency model should be also used. Besides, the surface under the cumulative ranking curve (SUCRA) values will carry out a possible range of interventions results by using OpenBUGS3.2.3, from 0 to 100%. Considering that the outcomes of this study are incidences of RIAE, the closer the value is to 100%, the worse the intervention effect will be.

Subgroup analysis

If related researches are sufficient, patients undergoing the same radiation dose can be regrouped in these studies. Therefore, it will bring with an analysis of acupuncture-related therapies for adverse effects induced by different radiation dosage.

Quality assessment

The Grades of Recommendations Assessment Development and Evaluation (GRADE) guideline will be introduced to assess the quality of evidence. The guideline divides the quality of evidence to high, moderate, low, very low.
Ethics and informed consents

Since this is a protocol for systematic literature research, ethical approval can be skipped. At the same time this protocol has been registered on INPLASY (https://inplasy.com/) with a registration ID INPLASY202070054.

Discussion

Radiotherapy is one of the three major treatments for cancer. According to a survey of WHO in 2017, it's estimated that about 45% of cancer could be cured, among which about 40% cured by radiotherapy (28). Obviously, cancer patients can get great benefit from radiotherapy if RIAE is under control. With an extensive application of acupuncture in clinical practice, researches concerning acupuncture therapy for RIAE appear in successions (22,29). Modern technology has suggested that acupuncture can modulate neurological processes within the central nervous system (30), stimulate the autonomic nervous system and increase peripheral blood flow (16), which generally benefits patients undergoing radiation despite mechanism remains partly understood (24,31). Since acupuncture theories and needling instruments gradually developed, a growing number of acupuncture therapies have emerged in the meantime, making clinical application a manifold yet tough decision as it remains inconclusive which treatment can reap the greatest benefits. Also, symptom management paired with type of therapies has remained to be studied. That's why we desire to conduct a network meta-analysis. Admittedly, there are some deficiencies existing in this review. The languages of literature are limited, which may lead to bias. Radiotherapy dose and acupoint prescription of acupuncture therapies will not be limited in eligible criteria, in this case, we will further present a subgroup analysis if permitting. The results of this protocol will be published in related journal, and a quick update will be made when supplements are required.

Appendix 2: Draft Eligibility Criteria

Primary screening

1. Is this study a clinical study?
   YES____ NO____ UNCLEAR____

2. Does this study describes cancer patients?
   YES____ NO____ UNCLEAR____

3. Does this study employ certain acupuncture therapy?
   YES____ NO____ UNCLEAR____

4. Does this study relate to radiotherapy-induced adverse effects?
   YES____ NO____ UNCLEAR____

5. Is this study peer-reviewed?
   YES____ NO____ UNCLEAR____

6. Does this study is written in Chinese or English?
   YES____ NO____ UNCLEAR____

If you answer NO to any of these questions, the citation/study will be excluded. All other citations will be included.

Secondary Screening

1. Is this study a RCT?
   YES____ NO____ UNCLEAR____

2. Does patients in this study undergo single radiation therapy, not accompanied by chemotherapy or other interventions possibly causing adverse effects?
   YES____ NO____ UNCLEAR____

3. Is acupuncture therapy used as prophylaxis or treatment in this study?
   YES____ NO____ UNCLEAR____

4. Does this study use acupuncture therapy or combined therapies as intervention?
   YES____ NO____ UNCLEAR____

5. Does this study record outcomes as required, such as the response rate of RIAE?
   YES____ NO____ UNCLEAR____

6. Does sample size of each group in this study >10?
   YES____ NO____ UNCLEAR____

If you answer NO to any of these questions, the citation/study will be excluded. All other full-text articles will be included.
